Lab 8: Association Rules

Assoc. Prof. Dr. Mohammed Al-Sarem
Taibah University, Information System
Department
3/19/2020

Lab Objectives:

The goal of this lab is to explain the role of association rules in mining hidden relationships in data. After completion of this lab, you will be able to:

Generate association rules using Apriori algorithm

Evaluate the goodness of the findings rules

Methodology

First you have to install the required library that allow you to run Apriori algorithm. Then, as usual, you have to load and read dataset. After executing the algorithm, a set of generated rules are found. Your task is to analyze these rules and reports only the most interesting.

In class task:

At the end of this lab, the student will be able to:

Explain how the Apriori algorithm works.

Extract rules from the generated set.

Evaluate the findings using Support and Confidence.

home task:

Complete your Course Project (See Home task in lab 5).

1. Frequent Itemsets via Apriori Algorithm

Apriori function to extract frequent itemsets for association rule mining. To work with apriori algorithm, first you have to install, in this time, mixtend library as follows:

add a new jupyter cell

write down the following code: pip install mlxtend Now, you can find the required algorithm by import it using the following:

from mlxtend.frequent_patterns import apriori

Generating Frequent Itemsets

Suppose we have the following transaction data as depicted in the Table below.

Tid Items bought

1 Drink, Nuts, Diaper

2 Drink, Coffee, Diaper

3 Drink, Diaper, Eggs

4 Nuts, Eggs, Milk

5 Nuts, Coffee, Diaper, Eggs, Milk

Table 1: Transaction Data

Exercise 1.1: The apriori function expects data in a one-hot encoded pandas DataFrame. Use the transaction data that is presented in the Table 1 and convert the them into 2 dimensional array. Display the output here!

```
[['Drink', 'Nuts', 'Diaper'],
  ['Drink', 'Coffee', 'Diaper'],
  ['Drink', 'Diaper', 'Eggs'],
  ['Nuts', 'Eggs', 'Milk'],
  ['Nuts', 'Coffee', 'Diaper', 'Eggs', 'Milk']]
```

Exercise 1.2: Display the dataset below! What do you see?

```
import pandas as pd
from mlxtend.preprocessing import
TransactionEncoder
TranEncod = TransactionEncoder()
te_ary =
TranEncod.fit(dataset).transform(dataset
)
df = pd.DataFrame(te_ary,
columns=TranEncod.columns_)
```

```
Seven Pepsi Nuts
                Milk Eggs Drink Diaper Cola Coffee
False False
           True False False True
                                 True False
False False False False
                          True
                                 True False
                                            True 1
False False False True True
                                True False
False False True True False False False
                                           False 3
False False True True False
                                True False
                                            True 4
 True True False False False False True
                                           False 5
```

df

Remember that to work with association rules, the algorithm required as input beside the dataset, the minimum support value :

```
\begin{aligned} & \text{Apriori}(T,\epsilon) \\ & L_1 \leftarrow \{ \text{large } 1 - \text{itemsets} \} \\ & k \leftarrow 2 \\ & \textbf{while } L_{k-1} \neq \emptyset \\ & C_k \leftarrow \{ c = a \cup \{b\} \mid a \in L_{k-1} \land b \not\in a, \{ s \subseteq c \mid |s| = k-1 \} \subseteq L_{k-1} \} \\ & \textbf{for transactions } t \in T \\ & D_t \leftarrow \{ c \in C_k \mid c \subseteq t \} \\ & \textbf{for candidates } c \in D_t \\ & count[c] \leftarrow count[c] + 1 \\ & L_k \leftarrow \{ c \in C_k \mid count[c] \geq \epsilon \} \\ & k \leftarrow k+1 \\ & \textbf{return } \bigcup_b L_k \end{aligned}
```

So, let us return the items and itemsets with at least 60% support.

```
apriori(df, min_support=0.6)
```

By default, apriori returns the column indices of the items, which may be useful in downstream operations such as association rule mining. For better readability, we can set

use_colnames=True to convert these integer values into the respective item names:

```
apriori(df, min_support=0.6, use_colnames=True)
    support
                  itemsets
 0
        0.8
                   (Diaper)
 1
        0.6
                    (Drink)
 2
        0.6
                    (Eggs)
 3
        0.6
                    (Nuts)
        0.6 (Diaper, Drink)
```

Exercise 1.3: Find the possible rules and calculate the confidence of each rule you find?

```
P(B|A) = |B \cap A| / |A| \\ Drink=3 \text{ Nuts}=3 \text{ Eggs}=3 \text{ Diaper}=4 \text{ Milk}=2 \text{ Coffee}=2 \\ Drink - Diaper=3/3*100=100\% \\ Diaper - Drink = 3/4*100=75\% \\ Diaper - Nuts = 2/4*100=50\% \\ Diaper - Coffee = 2/4*100=50\% \\ Diaper - Eggs = 2/4*100=50\% \\ Nuts - Diaper = 2/3*100=66.5\% \\ Nuts - Milk = 2/3*100=66.5\% \\ Nuts - Hilk = 2/3*100=66.5\% \\ Coffee - Diaper = 2/2*100=100\% \\ Eggs - Diaper = 2/3*100=66.5\% \\ Eggs - Nuts = 2/3*100=66.5\% \\ Eggs - Milk = 2/3*10
```

2. Selecting and Filtering Results

4 0.6 (Diaper, Drink)

Before moving ahead, let us decrease the minimum support to 30%. This leads to increase the number of returned items and itemsets. Let us now filter out these rules. The advantage of working with pandas DataFrames is that we can use its convenient features to filter the results. For instance, let's assume we are only interested in itemsets of length 2 that have a support of at least 50% percent. First, we create the frequent itemsets via apriori and add a new column that stores the length of each itemset:

Then, you can select the results that satisfy our desired criteria as follows:

Similarly, using the Pandas API, we can select entries based on the "itemsets" column:

```
frequent_itemsets[ frequent_itemsets['itemsets'] == {'Diaper', 'Drink'} ]
```

Good luck
